## CNT 4603, Spring 2009: Introduction

A practical hands-on approach

Also higher-level concepts

Expertise is distributed: system administration happens everywhere from your PC to large servers, and system administration is generally collaborative. Other people will help you solve problems and learn more

#### CNT 4603, Spring 2009: Introduction

The systems we will emphasize are Linux. We will also talk some about Solaris and Windows.

## CNT 4603, Spring 2090: Introduction

You may see occasionally see these abbreviations in course materials:

- $\longrightarrow$  USAH  $\rightarrow$  Unix System Administration Handbook (Nemeth et~al)
- $\mathbf{W}$  **W2K3**  $\rightarrow$  Mastering Windows Server 2003 (Minasi et al)

#### Introduction to Unix

Unix is now more than 30 years old

It began in 1969

See The Evolution of the Unix Time-sharing System by Dennis Ritchie

http://cm.bell-labs.com/cm/cs/who/dmr/hist.html

#### Introduction to Unix

Started at AT&T's Bell Labs, derived from MULTICS.

Initial hardware was a DEC PDP-7, and the filesystem was hierarchical but did not have pathnames

(i.e., there was no equivalent to a pathname such as /etc/hosts, it would just be hosts; directory information was kept in a special file called dd)

Rather than a product from a manufacturer, Unix began as collaboration with these goals:

- Simplicity
- Multi-user support
- Portability
- Universities could get source code easily

#### Introduction to Unix

- The development of early Unix was user-driven rather than corporate-driven
- Note that Linux and the BSDs (FreeBSD, OpenBSD, NetBSD) now flourish in similiar "open source" environments (http://www.freebsd.org, http://www.openbsd.org, http://www.netbsd.org)
- The first meeting of the **Unix User Group** was in May, 1974; this group would late become the **Usenix Association**

#### Introduction to Unix

You can watch the ever-varying open source world of Linux/BSD distributions at http://www.distrowatch.com/

## **A** History of Unix

In the beginning, processes were **very** different

- Originally
  - Each terminal only could have one active process
  - When creating a "child" process, the parent first closed all of its open files
  - Then the parent linked to the executable and opened it

Then the parent copied a bootstrap to the top of memory and jumped into the bootstrap

- The bootstrap copied the code for the new process over the parent's code and then jumped into it
- When the child did an exit, it first copied in the parent process code into its code area, and then jumped back into the parent code at the beginning

#### **Old Unix**

Today the parent uses a fork/exec/wait model:

- fork(2) (to create a new child process)
- m exec\*(2) (to have the child process start ex
  a new program)
- >>> wait\*(2) (to wait on the child (or at least
  on its status if non-blocking))

#### **Unix Today**

□ Linux: a complete Unix-compatible operating system

- Runs on huge array of hardware, from IBM's biggest machines down to commodity routers such as the Linksys WRT routers using DD-WRT
- Based on Linux Torvalds' kernel (he is still in charge of kernel development (2.6.28 is the current stable release), though now many people work on the kernel)
- The main Linux distributions we will use are

CentOS and Fedora; each includes a full development environment, X-Windows, NFS, office environment products (word processors, spreadsheets, etc), C, C++, Fortran, several mail systems (exim, postfix, and sendmail) and whole lot more (a full install is around 5 to 7 gigabytes)

- Linux is mostly POSIX.1 compliant
- FAQ: http://www.opengroup.org/austin/papers/posix\_faq.html

#### **Unix Today**

Solaris: a vendor Unix

Runs on Sun custom hardware and commodity PC hardware – and in virtual environments

#### Microsoft Windows

Windows 2008 Server is a proprietary system that follows in the NT and Windows Server 2003 family

- Windows 2008, like Windows 2003, has several varieties:
  - "Standard Edition" (Supports "Server Core")
  - "Henterprise Edition" (Supports "Server Core")
  - " "Datacenter Edition" (Supports "Server Core")

- "Windows Web Server"
- " 'Windows Storage Server'

#### Microsoft Windows

The Minasi book is an enjoyable, if voluminous, read

Windows has the advantage that it provides a single vendor solution, completely controlled by Microsoft

# System administration responsibilities (CIA)

- Availability of services and data
- Integrity of services and data
- Appropriate security

#### System administration duties

- Installing new hardware and software
- Updating and upgrading hardware and software
- Monitoring for problems
- Resolving problems
- Planning for growth and obsolence

Making backups

Recovering data from backups

## **Availability**

Lack of availability can have a large dollar impact on many businesses

The most common danger to availability is SPOFs (single points of failure)

#### **Availability**

SPOFs are generally cured by redundancy. Redundancy models:

 $\longrightarrow$  Cold  $\longrightarrow$  Good points: "guarantees" availability, but (1) typically most expensive (2) tends to require frequent testing (3) typically slow to bring live

#### **Availability**

Warm (dual-use hardware that is powered up and used for related but non-production purposes such as development or q/a)  $\rightarrow$  Typically good availability and less expensive than cold since the hardware has day-to-day use, but (1) tends to be one-offish and (2) tends to require frequent testing of switchover

#### **Availability**

Hot (redundant hardware in production) typically least expensive since it is in active production use and testing requirements tend to be less but more likely to have capacity problems in the event of partial failure

#### Integrity of data

For system administration purposes, often data integrity is implicitly enforced both at the hardware and the operating system level, such as CRCs for disk reads, parity in RAID-5 controllers, and so forth.

#### Integrity of data

However, it can also be an explicit issue, such as logical names that must be correct.

#### Integrity of data

Example: you create a soft link from the logical name for a package to its new implemention, say DBB-Current → DBB-1.8; however, inside of an update script, you somehow leave a single instance of a hard-coded DBB-1.7 (the old version) rather the logical name DBB-Current. When the script runs, the update now mixes the two packages DBB-1.8 and DBB-1.7.

#### **Data security**

This is a **big** topic, even from a pure system administration point of view.

Passive security: design your systems with security in mind.

#### **Data security**

Active security: (1) Searching for problems with tools such as Snort and Nessus (2) Forensically researching problems with tools such as with TCT.

# Some of the elements of Unix/Linux system administration: editors, scripting, and compilation

**Editors**: A lot of Unix/Linux system administration tasks revolve around editing various files. The best two choices for editing are the programs **vi** and **emacs**.

# Some of the elements of Unix/Linux system administration: editors, scripting, and compilation

Scripting: In addition to simple configuration files, another important subset of tasks that require editors are scripts. These scripts are used for various purposes, and often automating routine tasks such as running programs such as makewhatis.

# Some of the elements of Unix/Linux system administration: editors, scripting, and compilation

**Compilation**: Generally on Unix/Linux machines, **gcc** is a good choice for compilation. While it is not perfect, and the various generations of **gcc** can be somewhat frustrating to deal with, it is hard to beat the price.

## Unix/Linux system administration: editors

vi: It is almost always found somewhere on a Unix/Linux machine, often in the form of vim.

vi advantage: It is simple to learn. It has two modes, "motion" and "insert". In the "motion" mode, the most important keys are just

h: Move the cursor left.

■ I: Move the cursor right.

**j**: Move the cursor down.

# Unix/Linux system administration: editors

- **k**: Move the cursor up.
- i: Go into "insert" mode.
- ":": Execute an internal **vi** command of some sort. The most popular "w" for "write", "q" for "quit", and "

# Unix/Linux system administration: editors

wi disadvantage: While original vi is quite simple, it also is not very featureful. This isn't as much of a problem with vim, an updated version of vi. These extensions are not as logical as those emacs since they were created as an afterthought.

## Unix/Linux system administration: editors

emacs: Not always installed by default. In fact, in the last few years, default installation of Emacs in Unix/Linux distributions has become less common.

## Unix/Linux system administration: editors

is quite intuitive: each sequence of keystrokes can be mapped to a Emacs Lisp function. For instance, by default in TeX mode, the key "a" is just mapped to a function which inserts an "a", but the double quote key is mapped to insert first a pair of "and then the second time to insert a pair of closing" in accord with TEX's expectations.

## Unix/Linux system administration: editors

emacs disadvantage: It's not found on every machine.

emacs disadvantage: It's big.

# Unix/Linux system administration: scripting languages

**bash**: The "Bourne-Again SHell". Introduced the "readline" library. A comprehensive overhaul of the original Bourne shell.

perl5: The "Practical Extraction and Report Language". An amazing language in its own right; originally, it could be mistaken for line noise, much as the old TECO editor commands.

perl6: Currently, version 5 is very useful, though version 6 still hasn't jelled. My lecture notes for this class have used that "not jelled" phrase since 2003, it appears!
