Monte Carlo Methods: Numerical Experimental that Use Random Numbers

- A Monte Carlo method is any process that consumes random numbers
- 1. Each calculation is a numerical experiment
 - Subject to known and unknown sources of error
 - Should be reproducible by peers
 - Should be easy to run anew with results that can be combined to reduce the variance
- 2. Sources of errors must be controllable/isolatable
 - Programming/science errors under your control
 - Make possible RNG errors approachable
- 3. Reproducibility
 - Must be able to rerun a calculation with the same numbers

- Across different machines (modulo arithmetic issues)
- Parallel and distributed computers?

What are Random Numbers Used For?

- 1. Random numbers are used extensively in simulation, statistics, and in *Monte Carlo* computations
 - Simulation: use random numbers to "randomly pick" event outcomes based on statistical or experiential data
 - Statistics: use random numbers to generate data with a particular distribution to calculate statistical properties (when analytic techniques fail)
- 2. There are many Monte Carlo applications of great interest
 - Numerical quadrature "all Monte Carlo is integration"
 - Quantum mechanics: Solving Schrödinger's equation with Green's function Monte Carlo via random walks
 - Mathematics: Using the Feynman-Kac/path integral methods to solve partial differential equations with random walks
 - Defense: neutronics, nuclear weapons design
 - Finance: options, mortgage-backed securities

What are Random Numbers Used For?

- 3. There are many types of random numbers
 - "Real" random numbers: uses a 'physical source' of randomness
 - Pseudorandom numbers: deterministic sequence that passes tests of randomness
 - Quasirandom numbers: well distributed (low discrepancy) points

Why Monte Carlo?

1. Rules of thumb for Monte Carlo methods

- Good for computing linear functionals of solution (linear algebra, PDEs, integral equations)
- ► No discretization error but sampling error is O(N^{-1/2})
- High dimensionality is favorable, breaks the "curse of dimensionality"
- Appropriate where high accuracy is not necessary
- Often algorithms are "naturally" parallel
- 2. Exceptions
 - Complicated geometries often easy to deal with
 - Randomized geometries tractable
 - Some applications are insensitive to singularities in solution
 - Sometimes is the fastest high-accuracy algorithm (rare)

The Classic Monte Carlo Application: Numerical Integration 1. Consider computing $I = \int_0^1 f(x) dx$ 2. Conventional quadrature methods:

$$I \approx \sum_{i=1}^{N} w_i f(x_i)$$

• Rectangle:
$$w_i = \frac{1}{N}, x_i = \frac{i}{N}$$

• Trapezoidal:
$$w_i = \frac{2}{N}, w_1 = w_N = \frac{1}{N}, x_i = \frac{1}{N}$$

3. Monte Carlo quadrature

$$I \approx \frac{1}{N} \sum_{i=1}^{N} f(x_i), \quad x_i \sim U[0,1], \text{ i.i.d.}$$

4. Big advantage seen in multidimensional integration, consider (s-dimensions):

$$I = \int_{[0,1]^s} f(x_1, \ldots, x_s) \, dx_1 \ldots dx_s$$

The Classic Monte Carlo Application: Numerical Integration

- 1. Errors are significantly different, with *N* function evaluations we see the curse of dimensionality
 - Product trapezoidal rule: $Error = O(N^{-2/s})$
 - Monte Carlo: Error = $O(N^{-1/2})$ (indep. of s!!)
- 2. Note: the errors are deterministic for the trapezoidal rule whereas the MCM error is a variance bound
- 3. For s = 1, $E[f(x_i)] = I$ when $x_i \sim U[0, 1]$, so $E[\frac{1}{N} \sum_{i=1}^{N} f(x_i)] = I$, and $Var[\frac{1}{N} \sum_{i=1}^{N} f(x_i)] = Var[f(x_i)]/N$. $Var[f(x_i)] = \int_0^1 (f(x) - I)^2 dx$

Types of pseudorandom numbers

Pseudorandom Numbers

- Pseudorandom numbers mimic the properties of 'real' random numbers
- A. Pass statistical tests
- **B.** Reduce error is $O(N^{-\frac{1}{2}})$ in Monte Carlo
 - Some common pseudorandom number generators (RNG):
- 1. Linear congruential: $x_n = ax_{n-1} + c \pmod{m}$
- 2. Implicit inversive congruential: $x_n = a\overline{x_{n-1}} + c \pmod{p}$
- 3. Explicit inversive congruential: $x_n = a\overline{n} + c \pmod{p}$
- 4. Shift register: $y_n = y_{n-s} + y_{n-r} \pmod{2}$, r > s
- 5. Additive lagged-Fibonacci: $z_n = z_{n-s} + z_{n-r}$ $(mod 2^k), r > s$
- 6. Combined: $w_n = y_n + z_n \pmod{p}$
- 7. Multiplicative lagged-Fibonacci: $x_n = x_{n-s} \times x_{n-r}$ (mod 2^{k}), r > s

- Pseudorandom number generation
 - Properties of these pseudorandom numbers

Pseudorandom Numbers

- Some properties of pseudorandom number generators, integers: $\{x_n\}$ from modulo *m* recursion, and $U[0, 1], z_n = \frac{x_n}{m}$
- **A.** Should be a purely periodic sequence (e.g.: DES and IDEA are not provably periodic)
- **B.** Period length: $Per(x_n)$ should be large
- C. Cost per bit should be moderate (not cryptography)
- **D.** Should be based on theoretically solid and empirically tested recursions

E. Should be a totally reproducible sequence

RNG: A Practitioner's Overview

- Pseudorandom number generation

- Properties of these pseudorandom numbers

Pseudorandom Numbers Some common facts (rules of thumb) about pseudorandom

- number generators:
- 1. Recursions modulo a power-of-two are cheap, but have simple structure
- 2. Recursions modulo a prime are more costly, but have higher quality: use Mersenne primes: $2^{p} 1$, where *p* is prime, too
- 3. Shift-registers (Mersenne Twisters) are efficient and have good quality
- 4. Lagged-Fibonacci generators are efficient, but have some structural flaws
- 5. Combining generators is 'provably good'
- 6. Modular inversion is very costly
- 7. All linear recursions 'fall in the planes'
- 8. Inversive (nonlinear) recursions 'fall on hyperbolas'

Properties of these pseudorandom numbers

Periods of Pseudorandom Number Generators

- 1. Linear congruential: $x_n = ax_{n-1} + c \pmod{m}$, $Per(x_n) = m - 1, m$ prime, with *m* a power-of-two, $Per(x_n) = 2^k$, or $Per(x_n) = 2^{k-2}$ if c = 0
- 2. Implicit inversive congruential: $x_n = a\overline{x_{n-1}} + c \pmod{p}$, Per $(x_n) = p$
- 3. Explicit inversive congruential: $x_n = a\overline{n} + c \pmod{p}$, Per $(x_n) = p$
- 4. Shift register: $y_n = y_{n-s} + y_{n-r} \pmod{2}$, r > s, Per $(y_n) = 2^r - 1$
- 5. Additive lagged-Fibonacci: $z_n = z_{n-s} + z_{n-r}$ (mod 2^k), r > s, $Per(z_n) = (2^r - 1)2^{k-1}$
- 6. Combined: $w_n = y_n + z_n \pmod{p}$, $Per(w_n) = Icm(Per(y_n), Per(z_n))$
- 7. Multiplicative lagged-Fibonacci: $x_n = x_{n-s} \times x_{n-r}$ (mod 2^k), r > s, $Per(x_n) = (2^r - 1)2^{k-3}$

- Pseudorandom number generation
 - Properties of these pseudorandom numbers

Combining RNGs

- There are many methods to combine two streams of random numbers, {x_n} and {y_n}, where the x_n are integers modulo m_x, and y_n's modulo m_y:
- 1. Addition modulo one: $z_n = \frac{x_n}{m_x} + \frac{y_n}{m_y} \pmod{1}$
- 2. Addition modulo either m_x or m_y
- 3. Multiplication and reduction modulo either m_x or m_y
- 4. Exclusive "or-ing"
 - Rigorously provable that linear combinations produce combined streams that are "no worse" than the worst
 - Tony Warnock: all the above methods seem to do about the same

Parallelization of pseudorandom number generators

Splitting RNGs for Use In Parallel

- We consider splitting a single PRNG:
 - Assume $\{x_n\}$ has $Per(x_n)$
 - Has the fast-leap ahead property: leaping L ahead costs no more than generating $O(\log_2(L))$ numbers
- Then we associate a single block of length L to each parallel subsequence:
- Blocking:
 - First block: $\{x_0, x_1, ..., x_{L-1}\}$
 - Second : $\{x_L, x_{L+1}, \dots, x_{2L-1}\}$
 - *i*th block: $\{x_{(i-1)L}, x_{(i-1)L+1}, \dots, x_{iL-1}\}$
- The Leap Frog Technique: define the leap ahead of

$$\ell = \left| \frac{\operatorname{Per}(x_i)}{L} \right|$$

- First block: $\{x_0, x_\ell, x_{2\ell}, \dots, x_{(L-1)\ell}\}$
- Second block: {x₁, x_{1+ℓ}, x_{1+2ℓ},..., x_{1+(L-1)ℓ}}
 *i*th block: {x_i, x_{i+ℓ}, x_{i+2ℓ},..., x_{i+(L-1)ℓ}}

Parallelization of pseudorandom number generators

Splitting RNGs for Use In Parallel

- 3. The Lehmer Tree, designed for splitting LCGs:
 - Define a right and left generator: R(x) and L(x)
 - The right generator is used within a process
 - The left generator is used to spawn a new PRNG stream
 - Note: $L(x) = R^W(x)$ for some W for **all** x for an LCG
 - Thus, spawning is just jumping a fixed, W, amount in the sequence
- 4. Recursive Halving Leap-Ahead, use fixed points or fixed leap aheads:
 - First split leap ahead: $\left|\frac{\text{Per}(x_i)}{2}\right|$
 - *i*th split leap ahead: $\left|\frac{\operatorname{Per}(x_i)}{2^{l+1}}\right|$
 - This permits effective user of all remaining numbers in {x_n} without the need for a priori bounds on the stream length L

Parallelization of pseudorandom number generators

Generic Problems Parallelizing via Splitting

- 1. Splitting for parallelization is not scalable:
 - It usually costs O(log₂(Per(x_i))) bit operations to generate a random number
 - For parallel use, a given computation that requires L random numbers per process with P processes must have Per(x_i) = O((LP)^e)
 - ► Rule of thumb: never use more than √Per(x_i) of a sequence → e = 2
 - Thus cost per random number is not constant with number of processors!!

Parallelization of pseudorandom number generators

Generic Problems Parallelizing via Splitting

2. Correlations within sequences are generic!!

- Certain offsets within any modular recursion will lead to extremely high correlations
- Splitting in any way converts auto-correlations to cross-correlations between sequences
- Therefore, splitting generically leads to interprocessor correlations in PRNGs

Parallelization of pseudorandom number generators

New Results in Parallel RNGs: Using Distinct Parameterized Streams in Parallel

1. Default generator: additive lagged-Fibonacci,

 $x_n = x_{n-s} + x_{n-r} \pmod{2^k}, \ r > s$

- Very efficient: 1 add & pointer update/number
- Good empirical quality
- Very easy to produce distinct parallel streams
- 2. Alternative generator #1: prime modulus LCG,

 $x_n = ax_{n-1} + c \pmod{m}$

Choice: Prime modulus (quality considerations)

< □ > < 同 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- Parameterize the multiplier
- Less efficient than lagged-Fibonacci
- Provably good quality
- Multiprecise arithmetic in initialization

Parallelization of pseudorandom number generators

New Results in Parallel RNGs: Using Distinct Parameterized Streams in Parallel

3. Alternative generator #2: power-of-two modulus LCG,

 $x_n = ax_{n-1} + c \pmod{2^k}$

- Choice: Power-of-two modulus (efficiency considerations)
- Parameterize the prime additive constant
- Less efficient than lagged-Fibonacci
- Provably good quality
- Must compute as many primes as streams

Parallelization of pseudorandom number generators

Parameterization Based on Seeding

Consider the Lagged-Fibonacci generator:

 $x_n = x_{n-5} + x_{n-17} \pmod{2^{32}}$ or in general:

$$x_n = x_{n-s} + x_{n-r} \pmod{2^k}, \ r > s$$

- The seed is 17 32-bit integers; 544 bits, longest possible period for this linear generator is $2^{17\times32} - 1 = 2^{544} - 1$
- Maximal period is $Per(x_n) = (2^{17} 1) \times 2^{31}$
- integers is odd
- This seeding failure results in only even "random numbers"
- Are $(2^{17} 1) \times 2^{31 \times 17}$ seeds with full period
- Thus there are the following number of full-period equivalence classes (ECs):

$$E = \frac{(2^{17} - 1) \times 2^{31 \times 17}}{(2^{17} - 1) \times 2^{31}} = 2^{31 \times 16} = 2^{496}$$

Parallelization of pseudorandom number generators

The Equivalence Class Structure

With the "standard" l.s.b., b₀:

or a special b₀ (adjoining 1's):

Parallelization of pseudorandom number generators

Parameterization of Prime Modulus LCGs

- Consider only x_n = ax_{n-1} (mod m), with m prime has maximal period when a is a primitive root modulo m
- ▶ If α and a are primitive roots modulo m then $\exists l \text{ s.t. } gcd(l, m-1) = 1$ and $\alpha \equiv a^l \pmod{m}$
- If m = 2^{2ⁿ} + 1 (Fermat prime) then all odd powers of α are primitive elements also
- If m = 2q + 1 with q also prime (Sophie-Germain prime) then all odd powers (save the qth) of α are primitive elements

Parallelization of pseudorandom number generators

Parameterization of Prime Modulus LCGs

Consider x_n = ax_{n-1} (mod m) and y_n = a^ly_{n-1} (mod m) and define the full-period exponential-sum cross-correlation between then as:

$$C(j, l) = \sum_{n=0}^{m-1} e^{\frac{2\pi i}{m}(x_n - y_{n-j})}$$

then the Riemann hypothesis over finite-fields implies $|C(j, l)| \le (l-1)\sqrt{m}$

Parallelization of pseudorandom number generators

Parameterization of Prime Modulus LCGs

- Mersenne modulus: relatively easy to do modular multiplication
- ▶ With Mersenne prime modulus, $m = 2^p 1$ must compute $\phi_{m-1}^{-1}(k)$, the *k*th number relatively prime to m 1
- ► Can compute φ_{m-1}(x) with a variant of the Meissel-Lehmer algorithm fairly quickly:
 - ► Use partial sieve functions to trade off memory for more than 2^j operations, j = # of factors of m - 1
 - Have fast implementation for p = 31, 61, 127, 521, 607

Parallelization of pseudorandom number generators

Parameterization of Power-of-Two Modulus LCGs

- $x_n = ax_{n-1} + c_i \pmod{2^k}$, here the c_i 's are distinct primes
- Can prove (Percus and Kalos) that streams have good spectral test properties among themselves
- Best to choose $c_i \approx \sqrt{2^k} = 2^{k/2}$
- Must enumerate the primes, uniquely, not necessarily exhaustively to get a unique parameterization
- Note: in 0 ≤ i < m there are ≈ m/(log₂m) primes via the prime number theorem, thus if m ≈ 2^k streams are required, then must exhaust all the primes modulo ≈ 2^{k+log₂k} = 2^kk = mlog₂m
- Must compute distinct primes on the fly either with table or something like Meissel-Lehmer algorithm

Parallelization of pseudorandom number generators

Parameterization of MLFGs

1. Recall the MLFG recurrence:

 $x_n = x_{n-s} \times x_{n-r} \pmod{2^k}, r > s$

- 2. One of the *r* seed elements is even \rightarrow eventually all become even
- 3. Restrict to only odd numbers in the MLFG seeds
- 4. Allows the following parameterization for odd integers modulo a power-of-two $x_n = (-1)^{y_n} 3^{z_n} \pmod{2^k}$, where $y_n \in \{0, 1\}$ and where

•
$$y_n = y_{n-s} + y_{n-r} \pmod{2}$$

•
$$z_n = z_{n-s} + z_{n-r} \pmod{2^{k-2}}$$

5. Last recurrence means we can us ALFG parameterization, z_n , and map to MLFGs via modular exponentiation

Parallelization of pseudorandom number generators

Quality Issues in Serial and Parallel PRNGs

- Empirical tests (more later)
- Provable measures of quality:
- 1. Full- and partial-period discrepancy (Niederreiter) test equidistribution of overlapping *k*-tuples
- 2. Also full- $(k = Per(x_n))$ and partial-period exponential sums:

$$C(j,k) = \sum_{n=0}^{k-1} e^{\frac{2\pi i}{m}(x_n - x_{n-j})}$$

- -Pseudorandom number generation
 - Parallelization of pseudorandom number generators

Quality Issues in Serial and Parallel PRNGs

 For LCGs and SRGs full-period and partial-period results are similar

$$|C(\cdot, \operatorname{Per}(x_n))| < O(\sqrt{\operatorname{Per}(x_n)}) \\ |C(\cdot, j)| < O(\sqrt{\operatorname{Per}(x_n)})$$

► Additive lagged-Fibonacci generators have poor provable results, yet empirical evidence suggests |*C*(·, Per(*x_n*))| < *O*(√Per(*x_n*))

Parallelization of pseudorandom number generators

Parallel Neutronics: A Difficult Example

- 1. The structure of parallel neutronics
 - Use a parallel queue to hold unfinished work
 - Each processor follows a distinct neutron
 - Fission event places a new neutron(s) in queue with initial conditions
- 2. Problems and solutions
 - Reproducibility: each neutron is queued with a new generator (and with the next generator)
 - Using the binary tree mapping prevents generator reuse, even with extensive branching
 - A global seed reorders the generators to obtain a statistically significant new but reproducible result

RNG: A Practitioner's Overview

-Pseudorandom number generation

Parallelization of pseudorandom number generators

Many Parameterized Streams Facilitate Implementation/Use

- 1. Advantages of using parameterized generators
 - Each unique parameter value gives an "independent" stream
 - Each stream is uniquely numbered
 - Numbering allows for absolute reproducibility, even with MIMD queuing

・ロット (雪) ・ (ヨ) ・ (ヨ) ・ ヨ

- Effective serial implementation + enumeration yield a portable scalable implementation
- Provides theoretical testing basis

RNG: A Practitioner's Overview

-Pseudorandom number generation

Parallelization of pseudorandom number generators

Many Parameterized Streams Facilitate Implementation/Use

2. Implementation details

- Generators mapped canonically to a binary tree
- Extended seed data structure contains current seed and next generator
- Spawning uses new next generator as starting point: assures no reuse of generators
- 3. All these ideas in the Scalable Parallel Random Number Generators (SPRNG) library: http://sprng.org

Parallelization of pseudorandom number generators

Many Different Generators and A Unified Interface

- 1. Advantages of having more than one generator
 - An application exists that stumbles on a given generator
 - Generators based on different recursions allow comparison to rule out spurious results
 - Makes the generators real experimental tools
- 2. Two interfaces to the SPRNG library: simple and default
 - Initialization returns a pointer to the generator state: init_SPRNG()
 - Single call for new random number: SPRNG()
 - Generator type chosen with parameters in init_SPRNG()
 - Makes changing generator very easy
 - Can use more than one generator type in code
 - Parallel structure is extensible to new generators through dummy routines

・ロット (雪) (日) (日) (日)

-New directions for SPRNG

New Directions for SPRNG

- SPRNG: originally designed for distributed-memory multiprocessors
- New Intel Hardware RNG
- HPC architectures increasingly based on commodity chips with architectural variations
 - Microprocessors with more than one processor core (multicore)
 - The IBM cell processor (not very successful even though it was in the Sony Playstation)
 - Microprocessors with accelerators, most popular being GPGPUs (video games)
- We will consider only two of these:
 - Multicore support using OpenMP
 - GPU support using CUDA (Nvidia) and/or OpenCL (standard) < ロ > < 同 > < 三 > < 三 > < 三 > < ○ </p>

-Pseudorandom number generation

New directions for SPRNG

SPRNG Update Overview

- SPRNG uses independent full-period cycles for each processor
 - 1. Organizes the independent use of generators without communication
 - 2. Permits reproducibility
 - 3. Initialization of new full-period generators is slow for some generators
- A possible solution
 - 1. Keep the independent full-period cycles for "top-level" generators
 - 2. Within these (multicore processor/GPU) use cycle splitting to service threads

- Pseudorandom number generation

New directions for SPRNG

Experience with Multicore

- We have implemented an OpenMP version of SPRNG for multicore using these ideas
- OpenMP is now built into the main compilers, so it is easy to access
- Our experience has been
 - 1. It works as expected giving one access to Monte Carlo on all the cores
 - 2. Permits reproducibility but with some work: must know the number of threads
 - 3. Near perfect parallelization is expected and seen
 - 4. Comparison with independent spawning vs. cycle splitting is not as dramatic as expected
- Backward reproducibility is something that we can provide, but forward reproducibility is trickier
- This version is a prototype, but will be used for the eventual creation of the multicore version of SPRNG

- Pseudorandom number generation

New directions for SPRNG

Expectations for SPRNG on GPGPUs

- SPRNG for the GPU will be simple in principal, but harder for users
 - 1. The same technique that was used for multicore will work for GPUs with many of the same issues
 - 2. The concept of reproducibility will have to modified as well
 - 3. Successful exploitation of GPU threads will require that SPRNG calls be made to insure that the data and the execution are on the GPU
- The software development may not be the hardest aspect of this work
 - 1. Clear documentation with descriptions of common coding errors will be essential for success
 - An extensive library of examples will be necessary to provide most users with code close to their own to help use the GPU efficiently for Monte Carlo
- We are currently working on putting many Monte Carlo codes on GPUs in anticipation of this

-Quasirandom number generation

Quasirandom Numbers

- Many problems require uniformity, not randomness: "quasirandom" numbers are highly uniform deterministic sequences with small star discrepancy
- **Definition**: The star discrepancy D_N^* of x_1, \ldots, x_N :

$$D_N^* = D_N^*(x_1, ..., x_N) \\ = \sup_{0 \le u \le 1} \left| \frac{1}{N} \sum_{n=1}^N \chi_{[0,u)}(x_n) - u \right|,$$

where χ is the characteristic function

Discrepancy

Discrepancy Facts

Real random numbers have (the law of the iterated logarithm):

$$D_N^* = O(N^{-1/2}(\log \log N)^{-1/2})$$

Klaus F. Roth (Fields medalist in 1958) proved the following lower bound in 1954 for the star discrepancy of N points in s dimensions:

$$D_N^* \ge O(N^{-1}(\log N)^{\frac{s-1}{2}})$$

< □ > < 同 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- Sequences (indefinite length) and point sets have different "best discrepancies" at present
 - Sequence: $D_N^* \leq O(N^{-1}(\log N)^{s-1})$
 - Point set: $D_N^* \le O(N^{-1}(\log N)^{s-2})$

L The van der Corput sequence

Some Types of Quasirandom Numbers

- Must choose point sets (finite #) or sequences (infinite #) with small D^{*}_N
- ► Often used is the *van der Corput sequence* in base *b*: $x_n = \Phi_b(n-1), n = 1, 2, ...,$ where for $b \in \mathbb{Z}, b \ge 2$:

$$\Phi_b\left(\sum_{j=0}^{\infty} a_j b^j\right) = \sum_{j=0}^{\infty} a_j b^{-j-1}$$
 with $a_j \in \{0, 1, \dots, b-1\}$

Quasirandom number generation

L The van der Corput sequence

Some Types of Quasirandom Numbers

For the van der Corput sequence

$$\textit{ND}_{\textit{N}}^* \leq \frac{\log\textit{N}}{3\log 2} + \textit{O}(1)$$

With b = 2, we get {1/2, 1/4, 3/4, 1/8, 5/8, 3/8, 7/8...}
With b = 3, we get {1/3, 2/3, 1/9, 4/9, 7/9, 2/9, 5/9, 8/9...}

Quasirandom number generation

Methods of quasirandom number generation

Some Types of Quasirandom Numbers

- Other small D_N^* points sets and sequences:
- 1. Halton sequence: $\mathbf{x}_n = (\Phi_{b_1}(n-1), \dots, \Phi_{b_s}(n-1)),$ $n = 1, 2, \dots, D_N^* = O(N^{-1}(\log N)^s)$ if b_1, \dots, b_s pairwise relatively prime
- 2. Hammersley point set:
 - $\mathbf{x}_n = (\frac{n-1}{N}, \Phi_{b_1}(n-1), \dots, \Phi_{b_{s-1}}(n-1)), n = 1, 2, \dots, N,$ $D_N^* = O(N^{-1}(\log N)^{s-1})$ if b_1, \dots, b_{s-1} are pairwise relatively prime

Some Types of Quasirandom Numbers

- 3. Ergodic dynamics/Weyl sequence: $\mathbf{x}_n = \{n\alpha\}$ or $\mathbf{x}_n = \mathbf{x}_{n-1}\alpha \pmod{1}$, where $\alpha = (\alpha_1, \ldots, \alpha_s)$ is irrational and $\alpha_1, \ldots, \alpha_s$ are linearly independent over the rationals then for almost all $\alpha \in \mathbb{R}^s$, $D_N^* = O(N^{-1}(\log N)^{s+1+\epsilon})$ for all $\epsilon > 0$
- 4. Other methods of generation
 - Method of good lattice points (Sloan and Joe)
 - Sobol sequences
 - Faure sequences (more later)
 - Niederreiter sequences

-Quasirandom number generation

Methods of quasirandom number generation

Continued-Fractions and Irrationals

Infinite continued-fraction expansion for choosing good irrationals:

$$r = a_0 + rac{1}{a_1 + rac{1}{a_2 + \dots}}$$

 $a_i \leq K \longrightarrow$ sequence is a low-discrepancy sequence Choose all $a_i = 1$. Then

$$r = 1 + \frac{1}{1 + \frac{1}{1 + \dots}}$$

is the golden ratio.

```
0.618, 0.236, 0.854, 0.472, 0.090, \ldots
```

Irrational sequence in more dimensions is not a low-discrepancy sequence.

Quasirandom number generation

Methods of quasirandom number generation

Lattice

- Fixed N
- Generator vector $\vec{g} = (g_1, \dots, g_d) \in \mathbb{Z}^d$.

We define a rank-1 lattice as

$$\mathcal{P}_{\text{lattice}} := \left\{ ec{x_i} = rac{ec{g}}{N} \mod 1
ight\}.$$

-Quasirandom number generation

Methods of quasirandom number generation

Lattice

- After N points the sequence repeats itself,
- Projection on each axis gives the set $\{\frac{0}{N}, \frac{1}{N}, \dots, \frac{N-1}{N}\}$.

Not every generator gives a good point set. E.g. $g_1 = g_2 = \cdots = g_d = 1$, gives $\{(\frac{i}{N}, \dots, \frac{i}{N})\}$.

-Quasirandom number generation

Methods of quasirandom number generation

Some Types of Quasirandom Numbers

1. Another interpretation of the v.d. Corput sequence:

- Define the *i*th ℓ-bit "direction number" as: v_i = 2ⁱ (think of this as a bit vector)
- ► Represent n 1 via its base-2 representation n-1 = b_{ℓ-1}b_{ℓ-2}...b₁b₀
- Thus we have $\Phi_2(n-1) = 2^{-\ell} \bigoplus_{i=0, \ b_i=1}^{i=\ell-1} v_i$
- 2. The Sobol sequence works the same!!
 - Use recursions with a primitive binary polynomial define the (dense) v_i
 - The Sobol sequence is defined as:

$$s_n = 2^{-\ell} \bigoplus_{i=0, b_i=1}^{i=\ell-1} v_i$$

Use Gray-code ordering for speed

- Quasirandom number generation
 - Methods of quasirandom number generation

Some Types of Quasirandom Numbers

- ► (t, m, s)-nets and (t, s)-sequences and generalized Niederreiter sequences
- 1. Let $b \ge 2$, s > 1 and $0 \le t \le m \in \mathbb{Z}$ then a *b*-ary box, $J \subset [0, 1)^s$, is given by

$$J=\prod_{i=1}^{s}[\frac{a_i}{b^{d_i}},\frac{a_i+1}{b^{d_i}})$$

where $d_i \ge 0$ and the a_i are *b*-ary digits, note that $|J| = b^{-\sum_{i=1}^{s} d_i}$

-Quasirandom number generation

Methods of quasirandom number generation

Some Types of Quasirandom Numbers

- A set of b^m points is a (t, m, s)-net if each b-ary box of volume b^{t-m} has exactly b^t points in it
- 3. Such (t, m, s)-nets can be obtained via Generalized Niederreiter sequences, in dimension *j* of *s*: $y_i^{(j)}(n) = C^{(j)}a_i(n)$, where *n* has the *b*-ary representation $n = \sum_{k=0}^{\infty} a_k(n)b^k$ and $x_i^{(j)}(n) = \sum_{k=1}^{m} y_k^{(j)}(n)q^{-k}$

Randomization and Derandomization

Randomization of the Faure Sequence

- 1. A problem with all QRNs is that the Koksma-Hlawka inequality provides no practical error estimate
- 2. A solution is to randomize the QRNs and then consider each randomized sequence as providing an independent sample for constructing confidence intervals
- 3. Consider the *s*-dimensional Faure series is: $(\phi_p(C^{(0)}(n)), \phi_p(C^{(1)}(n)), \dots, \phi_p(P^{s-1}(n)))$
 - ► *p* > *s* is prime
 - $C^{(j-1)}$ is the generator matrix for dimension $1 \le j \le s$
 - For Faure $C^{(j)} = P^{j-1}$ is the Pascal matrix:
 - $P_{r,k}^{j-1} = \binom{r-1}{k-1}(j-1)^{(r-k)} \pmod{p}$

- -Quasirandom number generation
 - Randomization and Derandomization

Another Reason for Randomization

QRNs have inherently bad low-dimensional projections

-Quasirandom number generation

-Randomization and Derandomization

Another Reason for Randomization

Randomization (scrambling) helps

-Quasirandom number generation

Randomization and Derandomization

General Randomization Techniques

1. Random shifting: $z_n = x_n + r \pmod{1}$

- $x_n \in [0, 1]^s$ is the original QRN
- $r \in [0, 1]^s$ is a random point
- $z_n \in [0, 1]^s$ scrambled point
- 2. Digit permutation
 - Nested scrambling (Owen)
 - Single digit scrambling like linear scrambling
- 3. Randomization of the generator matrices, i.e. Tezuka's GFaure, $C^{(j)} = A^{(j)}P^{j-1}$ where A^j is a random nonsingular lower-triangular matrix modulo p

-Quasirandom number generation

-Randomization and Derandomization

Derandomization and Applications

- 1. Given that a randomization leads to a family of QRNs, is there a best?
 - Must make the family small enough to exhaust over, so one uses a small family of permutations like the linear scramblings
 - The must be a quality criterion that is indicative and cheap to evaluate
- 2. Applications of randomization: tractable error bounds, parallel QRNs
- 3. Applications of derandomization: finding more rapidly converging families of QRNs

Future Work on Random Numbers (not yet completed)

- 1. SPRNG and pseudorandom number generation work
 - New generators: Well, Mersenne Twister
 - Spawn-intensive/small-memory footprint generators: MLFGs
 - C++ implementation
 - Grid-based tools
 - More comprehensive testing suite; improved theoretical tests
 - New version incorporating the completed work

Future Work on Random Numbers (not yet completed)

2. Quasirandom number work

- Scrambling (parameterization) for parallelization
- Optimal scramblings
- Grid-based tools
- Application-based comparision/testing suite
- Comparison to sparse grids
- "QPRNG"
- 3. Commercialization of SPRNG
 - FSU-supported startup company
 - Commercial licenses and SPRNG consulting
 - Funds will support continued development and support
 - SPRNG will continue to be free to academic and government researchers
